Alert Detail

No Anti-CSRF tokens were found in a HTML submission form.

A cross-site request forgery is an attack that involves forcing a victim to send an HTTP request to a target destination without their knowledge or intent in order to perform an action as the victim. The underlying cause is application functionality using predictable URL/form actions in a repeatable way. The nature of the attack is that CSRF exploits the trust that a web site has for a user. By contrast, cross-site scripting (XSS) exploits the trust that a user has for a web site. Like XSS, CSRF attacks are not necessarily cross-site, but they can be. Cross-site request forgery is also known as CSRF, XSRF, one-click attack, session riding, confused deputy, and sea surf.

CSRF attacks are effective in a number of situations, including:

Description

- * The victim has an active session on the target site.
- * The victim is authenticated via HTTP auth on the target site.
- * The victim is on the same local network as the target site.

CSRF has primarily been used to perform an action against a target site using the victim's privileges, but recent techniques have been discovered to disclose information by gaining access to the response. The risk of information disclosure is dramatically increased when the target site is vulnerable to XSS, because XSS can be used as a platform for CSRF, allowing the attack to operate within the bounds of the same-origin policy.

Instances

Phase: Architecture and Design

Use a vetted library or framework that does not allow this weakness to occur or provides

constructs that make this weakness easier to avoid.

For example, use anti-CSRF packages such as the OWASP CSRFGuard.

Phase: Implementation

Ensure that your application is free of cross-site scripting issues, because most CSRF defenses can be bypassed using attacker-controlled script.

Phase: Architecture and Design

Generate a unique nonce for each form, place the nonce into the form, and verify the nonce upon

receipt of the form. Be sure that the nonce is not predictable (CWE-330).

Solution Note that this can be bypassed using XSS.

Identify especially dangerous operations. When the user performs a dangerous operation, send a

separate confirmation request to ensure that the user intended to perform that operation.

Note that this can be bypassed using XSS.

Use the ESAPI Session Management control.

This control includes a component for CSRF.

Do not use the GET method for any request that triggers a state change.

Phase: Implementation

Check the HTTP Referer header to see if the request originated from an expected page. This could break legitimate functionality, because users or proxies may have disabled sending the

Referer for privacy reasons.

Solution

Review the source code of this page. Implement custom error pages. Consider implementing a mechanism to provide a unique error reference/identifier to the client (browser) while logging the

details on the server side and not exposing them to the user.

Medium Content Security Policy (CSP) Header Not Set

Content Security Policy (CSP) is an added layer of security that helps to detect and mitigate certain types of attacks, including Cross Site Scripting (XSS) and data injection attacks. These attacks are used for everything from data theft to site defacement or distribution of malware. CSP provides a set of standard HTTP headers that allow website owners to declare approved sources of content that browsers should be allowed to load on that page — covered types are JavaScript, CSS, HTML frames, fonts, images and embeddable objects such as Java applets, ActiveX, audio

and video files.

Instances 11

Modern Web browsers support the Content-Security-Policy and X-Frame-Options HTTP headers.

Ensure one of them is set on all web pages returned by your site/app.

Solution If you expect the page to be framed only by pages on your server (e.g. it's part of a FRAMESET)

then you'll want to use SAMEORIGIN, otherwise if you never expect the page to be framed, you should use DENY. Alternatively consider implementing Content Security Policy's "frame-ancestors"

directive.

Other Info

This issue still applies to error type pages (401, 403, 500, etc.) as those pages are often still

affected by injection issues, in which case there is still concern for browsers sniffing pages away from their actual content type. At "High" threshold this scan rule will not alert on client or server

error responses.

Other Info

This issue still applies to error type pages (401, 403, 500, etc.) as those pages are often still

affected by injection issues, in which case there is still concern for browsers sniffing pages away from their actual content type. At "High" threshold this scan rule will not alert on client or server

error responses.

Instances 11

Ensure that the application/web server sets the Content-Type header appropriately, and that it sets

the X-Content-Type-Options header to 'nosniff' for all web pages.

Solution If possible, ensure that the end user uses a standards-compliant and modern web browser that

does not perform MIME-sniffing at all, or that can be directed by the web application/web server to

not perform MIME-sniffing.

Informational Authentication Request Identified

The given request has been identified as an authentication request. The 'Other Info' field contains

a set of key=value lines which identify any relevant fields. If the request is in a context which has an Authentication Method set to "Auto-Detect" then this rule will change the authentication to

match the request identified.

Informational **User Controllable HTML Element Attribute (Potential XSS)**

This check looks at user-supplied input in query string parameters and POST data to identify Description where certain HTML attribute values might be controlled. This provides hot-spot detection for XSS

(cross-site scripting) that will require further review by a security analyst to determine exploitability.

URL http://192.168.216.121/login.php

POST Method Parameter form

Attack

Evidence

Other Info

User-controlled HTML attribute values were found. Try injecting special characters to see if XSS might be possible. The page at the following URL: http://192.168.216.121/login.php appears to

include user input in: a(n) [button] tag [type] attribute The user input found was: form=submit The

user-controlled value was: submit

URL http://192.168.216.121/login.php

Method **POST** Parameter form
